OCTOBER, 1957

## Synthesis of the Elements in Stars

E. MARGARET BURBIDGE, G. R. BURBIDGE, WILLIAM A. FOWLER, AND F. HOYLE

*Kellogg Radiation Laboratory, California Institute of Technology, and  
Mount Wilson and Palomar Observatories, Carnegie Institution of Washington,  
California Institute of Technology, Pasadena, California*

"It is the stars, The stars above us, govern our conditions";  
(*King Lear*, Act IV, Scene 3)

but perhaps

"The fault, dear Brutus, is not in our stars, But in ourselves,"  
(*Julius Caesar*, Act I, Scene 2)

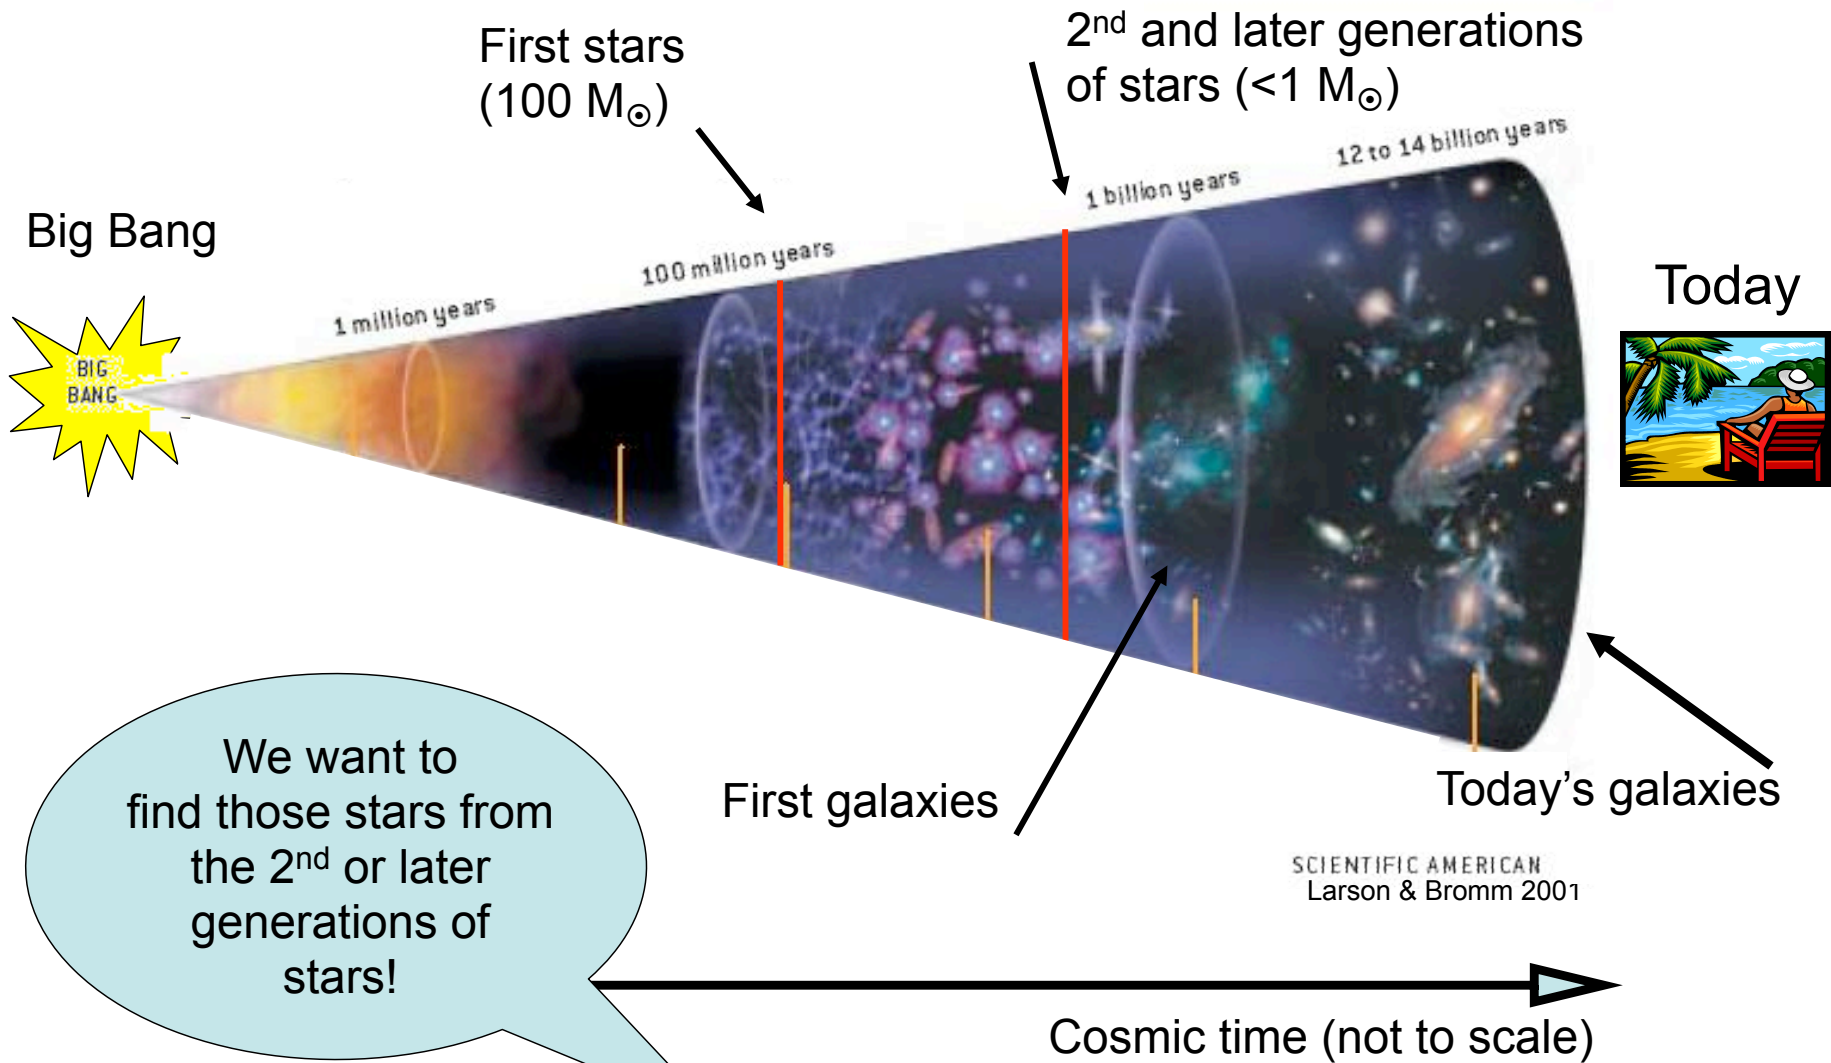

XI. Variations in Chemical Composition among Stars, and Their Bearing on the Various Synthesizing Processes.....	620
A. Hydrogen Burning and Helium Burning.....	621
B. $\alpha$ Process.....	626
C. Synthesis of Elements in the Iron Peak of the Abundance Curve, and the Aging Effect as It Is Related to This and Other Types of Element Synthesis.....	626
D. $\kappa$ Process.....	627
E. $r$ Process.....	629
F. $\phi$ Process.....	629
Element Synthesis in Surfaces of Stars.....	629

### E. $r$ Process

The outstanding piece of observational evidence that this takes place is given by the explanation of the light curves of supernovae of Type I as being due to the decay of  $\text{Cf}^{254}$  (Bu56, Ba56), together with some other isotopes produced in the  $r$  process. Further evidence can be obtained only by interpreting the spectra of Type I supernovae, a problem which has so far remained unsolved.

We have since discovered old stars with  $r$ -process enhancement!

# A LONG TIME AGO...

# CHEMICAL EVOLUTION

We are made of stardust!

Old stars contain fewer elements  
(e.g. iron) than younger stars

hydrogen
1
<b>H</b>
1.0079

*Astronomer's  
Periodic Table*

helium
2
<b>He</b>
4.0026

**Metals Z**

We look for the stars  
with the least amounts  
of elements heavier  
than H and He!

# Extremely Metal-poor Stars

## Facts and Definitions

- Fe traces the overall stellar metal content
- Fe is easy to measure
- $[\text{Fe}/\text{H}] = \log_{10}(\text{N}_{\text{Fe}}/\text{N}_{\text{H}}) - \log_{10}(\text{N}_{\text{Fe}}/\text{N}_{\text{H}})_{\text{sun}}$
- Lower  $[\text{Fe}/\text{H}] \longrightarrow$  Older Star
- $[\text{Fe}/\text{H}] \leq -3 \longrightarrow \sim 1$  progenitor supernova produced that iron

# The Milky Way

How common are  
r-process metal-  
poor stars?

~3-5% of metal-poor  
stars w/  $[Fe/H] < -2.5$   
(Barklem et al. 2005)

=> Only ~30 stars  
known so far w/  
 $[Eu/Fe] > 1.0$ , i.e.  
clear r-process  
pattern above Ba

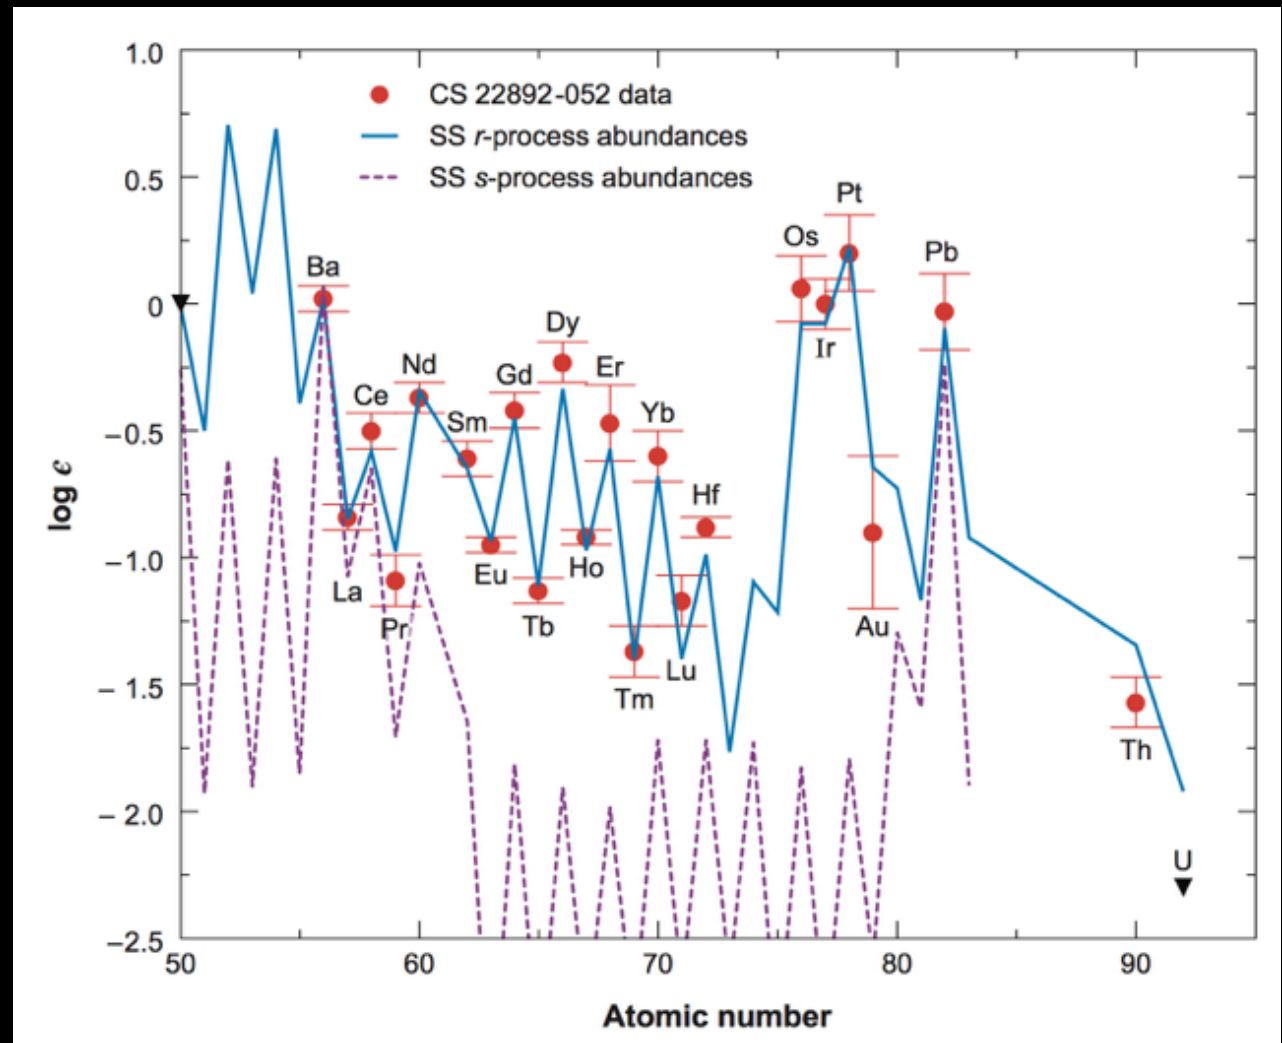

=> More stars known  
with lower levels of  
 $0.3 < [Eu/Fe] < 1.0$ ;  
unclear what lowest  
level is

=> Origin of these stars unknown

# Universal r-process pattern

- r-process abundance *pattern* the same in the Sun and metal-poor stars
- r-process stars all extremely metal poor ( $[Fe/H] \sim -3$ )

Snedden et al. 2008

# The Big Question

★ **What is the (dominant) astrophysical site of the r-process?**

➔ Core-collapse supernovae

➔ Neutron star mergers

➔ Others (e.g., magnetars)

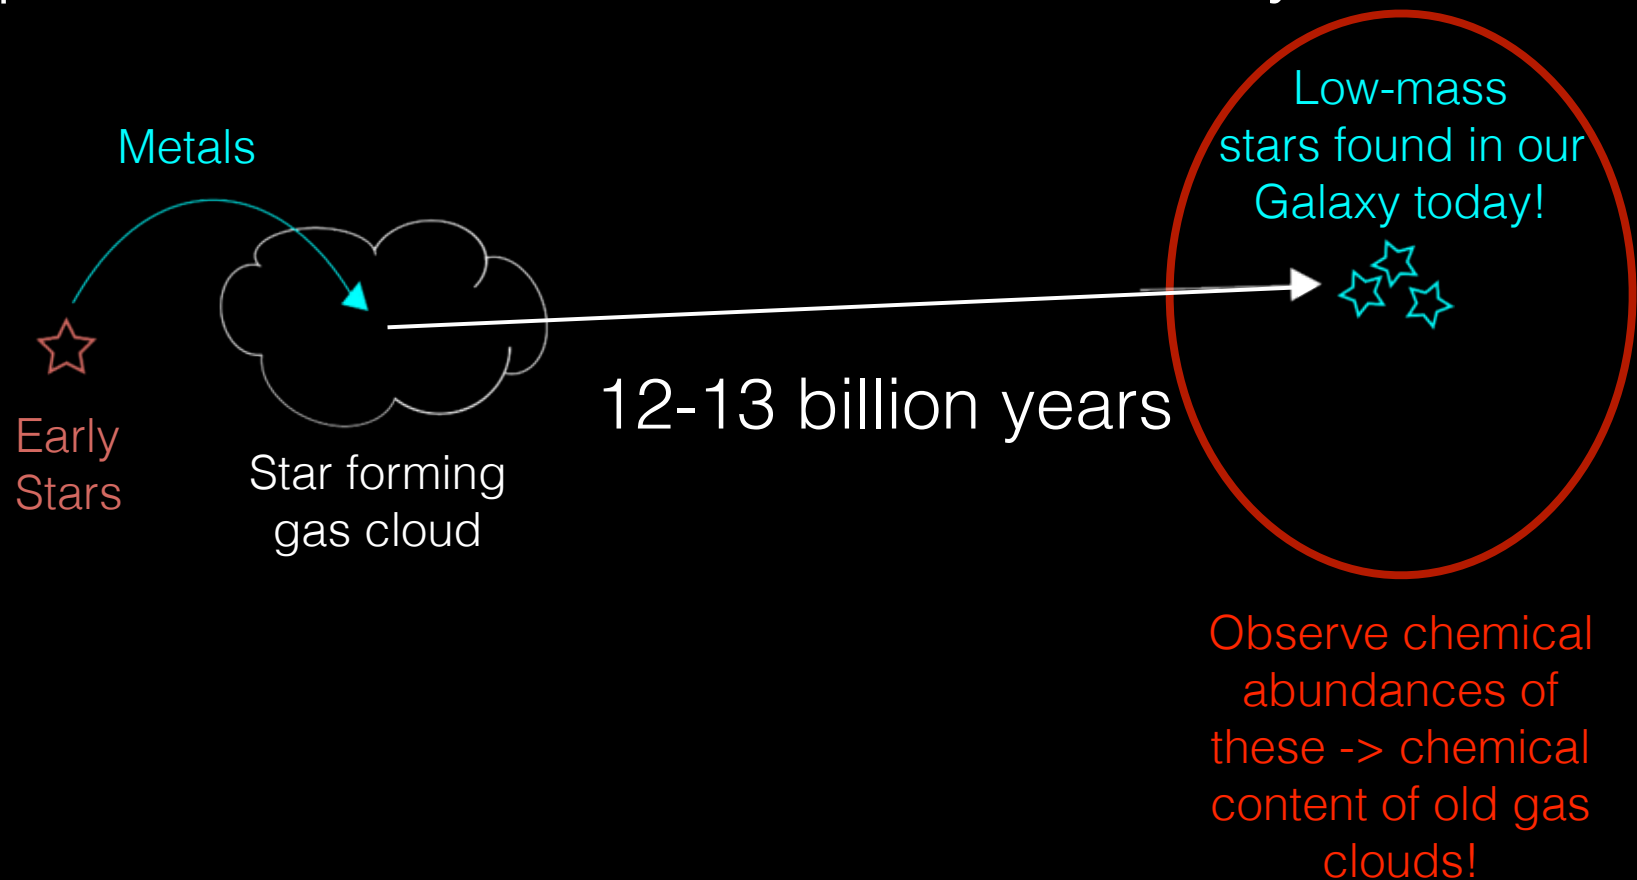

★ **What is the rate and yield of the event?**

★ **Does the dominant site change?**

# Clues to the r-process site

- **Stellar Archaeology:** using metal-poor stars to probe the chemical content of the early universe

# Clues to the r-process site

- **Stellar Archaeology:** using metal-poor stars to probe the chemical content of the early universe

**$[Fe/H] \leq -3 \Rightarrow$  Only  $\sim 1$  progenitor supernova produced that iron**

Observe chemical abundances of these  $\rightarrow$  chemical content of old gas clouds!

# Core-collapse supernova

SN are common; produce light elements with  $Z < 30$ ;

Responsible for those elements when observed in metal-poor stars

**Yield:**

$10^{-5} M_{\text{sun}}$  of wind material

$10^{-6} M_{\text{sun}}$  of r-process material

$10^{-7.5} M_{\text{sun}}$  of Eu

Woosley and Janka 2005

# Supernova enrichment

~13 Gyr  
of galaxy  
assembly

Big  
Bang

First/early stars  
explode

Metal-poor stars form  
from enriched gas...

...are found  
in the Milky Way today

## How it works:

- ✓ Fast enrichment; small & steady r-process yields
- ✓ Metal-poor stars only need one/few progenitors

**BUT...** Theoretical difficulties for r-process nucleosynthesis (e.g. Arcones et al.)

# Neutron star binary merger

## Rare

One binary per  
~1000- 2000  
supernovae

## Long(er) enrichment timescale

Inspiral time of NSM takes time; >100 Myr

## Yield:

$10^{-3}$  -  $10^{-2} M_{\text{sun}}$  of r-process material

$\Rightarrow 10^{-4.5} M_{\text{sun}}$  of Eu

Image Credit: Daniel Price (U/Exeter) and Stephan Rosswog (Int. U/Bremen)

# Indirect observations of local r-process nucleosynthesis

- Short gamma ray burst  $\leftrightarrow$  Neutron star merger
- Afterglow from decay of radioactive r-process elements detected in 2013
- Also see radioactive deep sea measurements  
Wallner et al. 2015  
Hotokezaka et al. 2015

Tanvir et al. 2013

Let's consider something new...!

# New Milky Way Satellites

image credit: H. Jerjen & ESO (background)

# Reticulum II

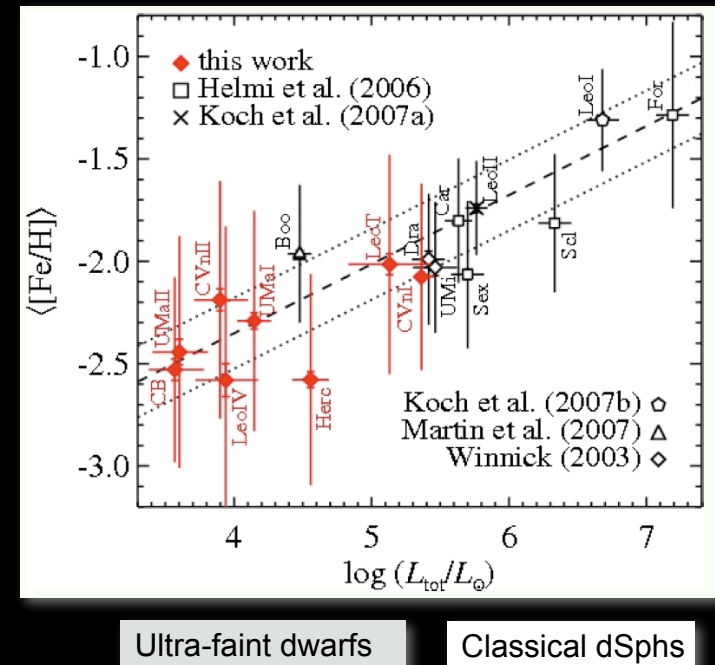

Dark Energy Survey

# Ultra-faint dwarf galaxies properties (UFDs)

- ✓ Low luminosity (300 - 3,000  $L_{\text{sun}}$ )
- ✓ Dark-matter-dominated ( $M/L > 100$ )
- ✓ Metal-poor (Mean  $[\text{Fe}/\text{H}] \sim -2$ )
- ✓ Stars are old (Mean age  $13.3 \pm 1$  Gyr)
- ✓ Few generations of star formation

# Light elements

Ret II stars have similar abundances to UFD and halo stars

**Core-collapse supernovae are primary metal source**

# Stars in *first nine* UFDs have low neutron-capture element abundances

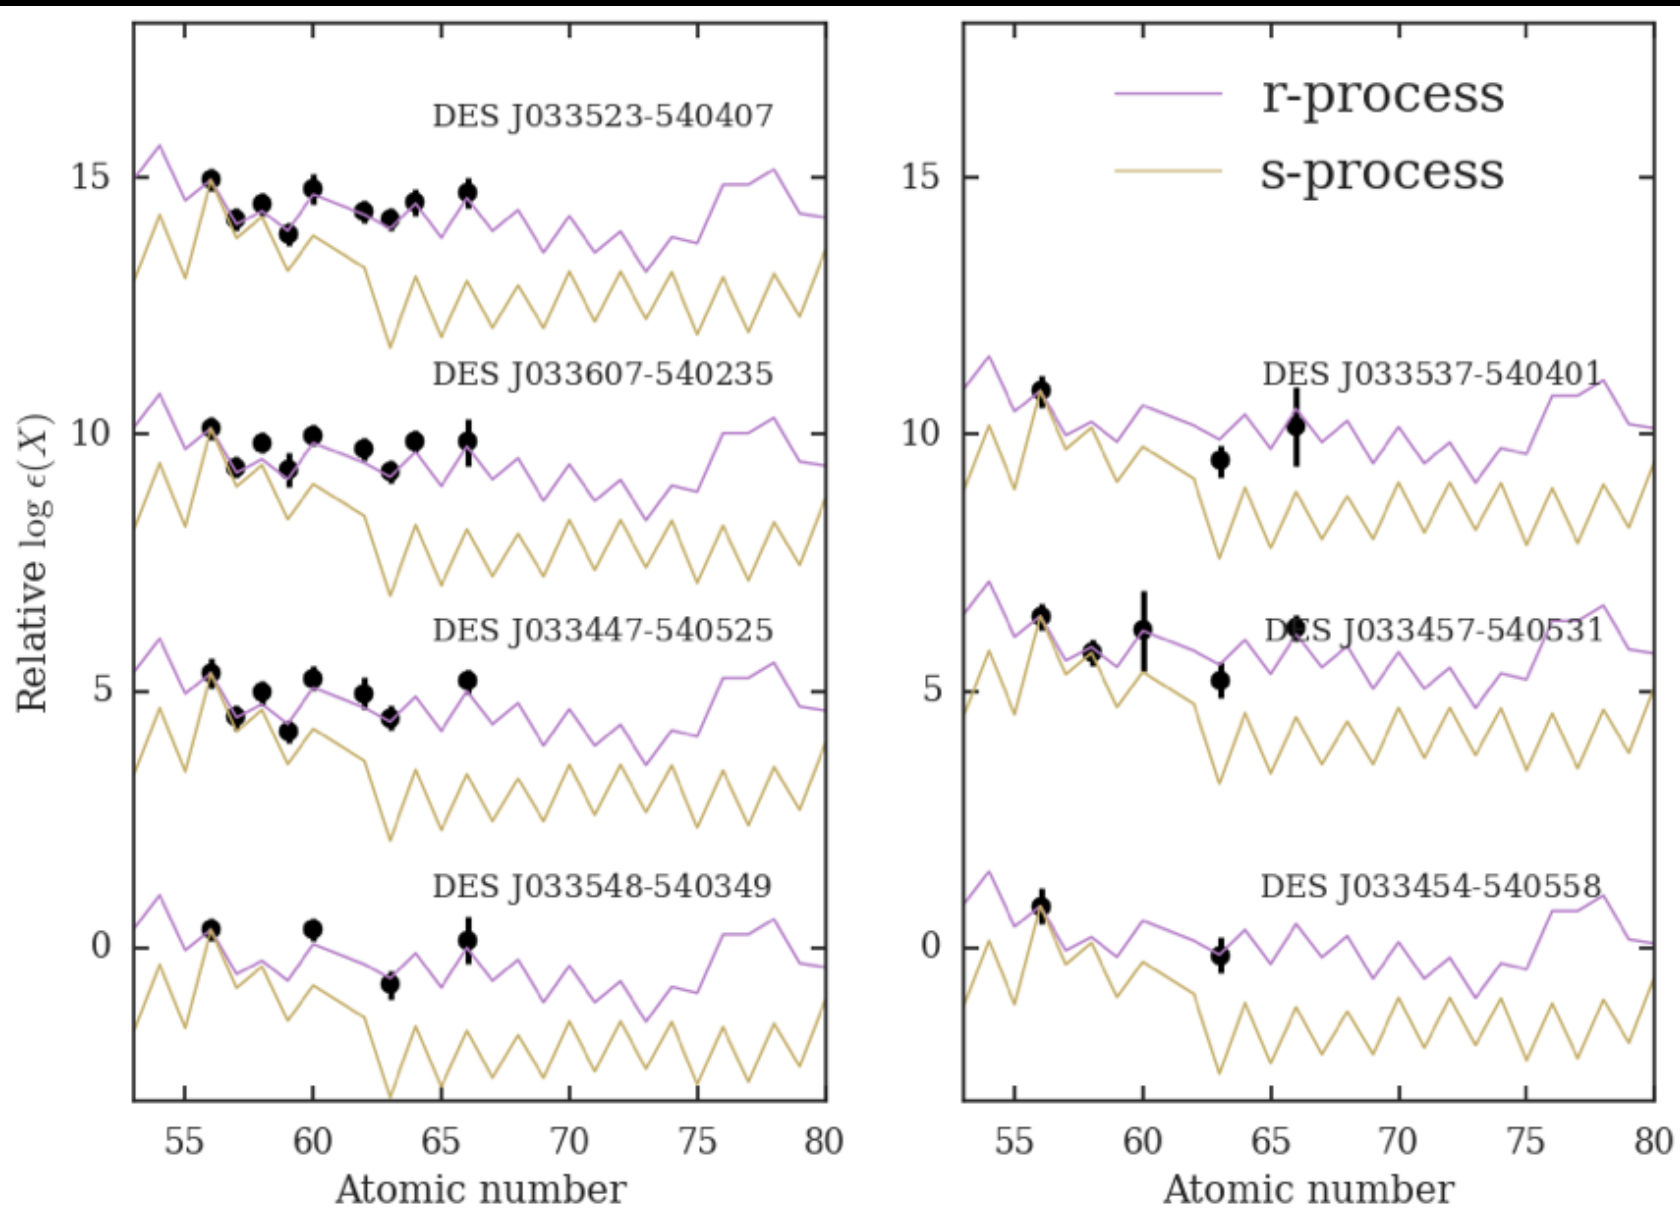

**UFD  
star**

**r-process  
star**

# All Ret II stars match r-process pattern

# UFD neutron-capture abundances *before* Reticulum II

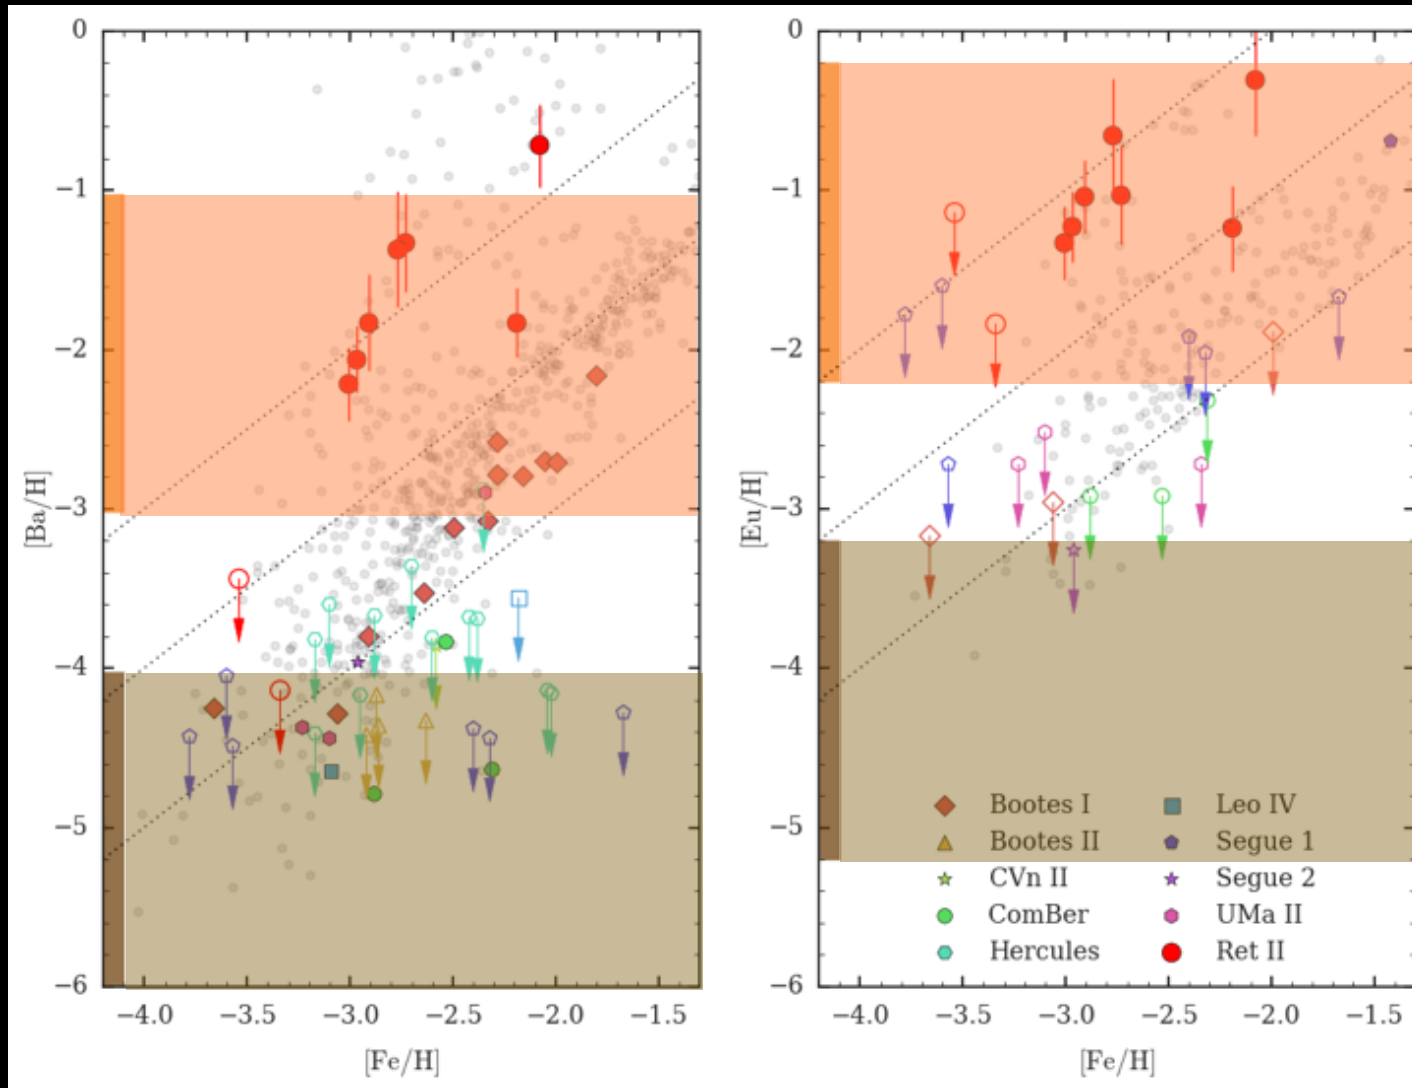

# Ret II stars $>100\times$ higher neutron-capture element abundances than other UFDs

# Ret II abundance consistent with neutron star merger

Neutron star merger

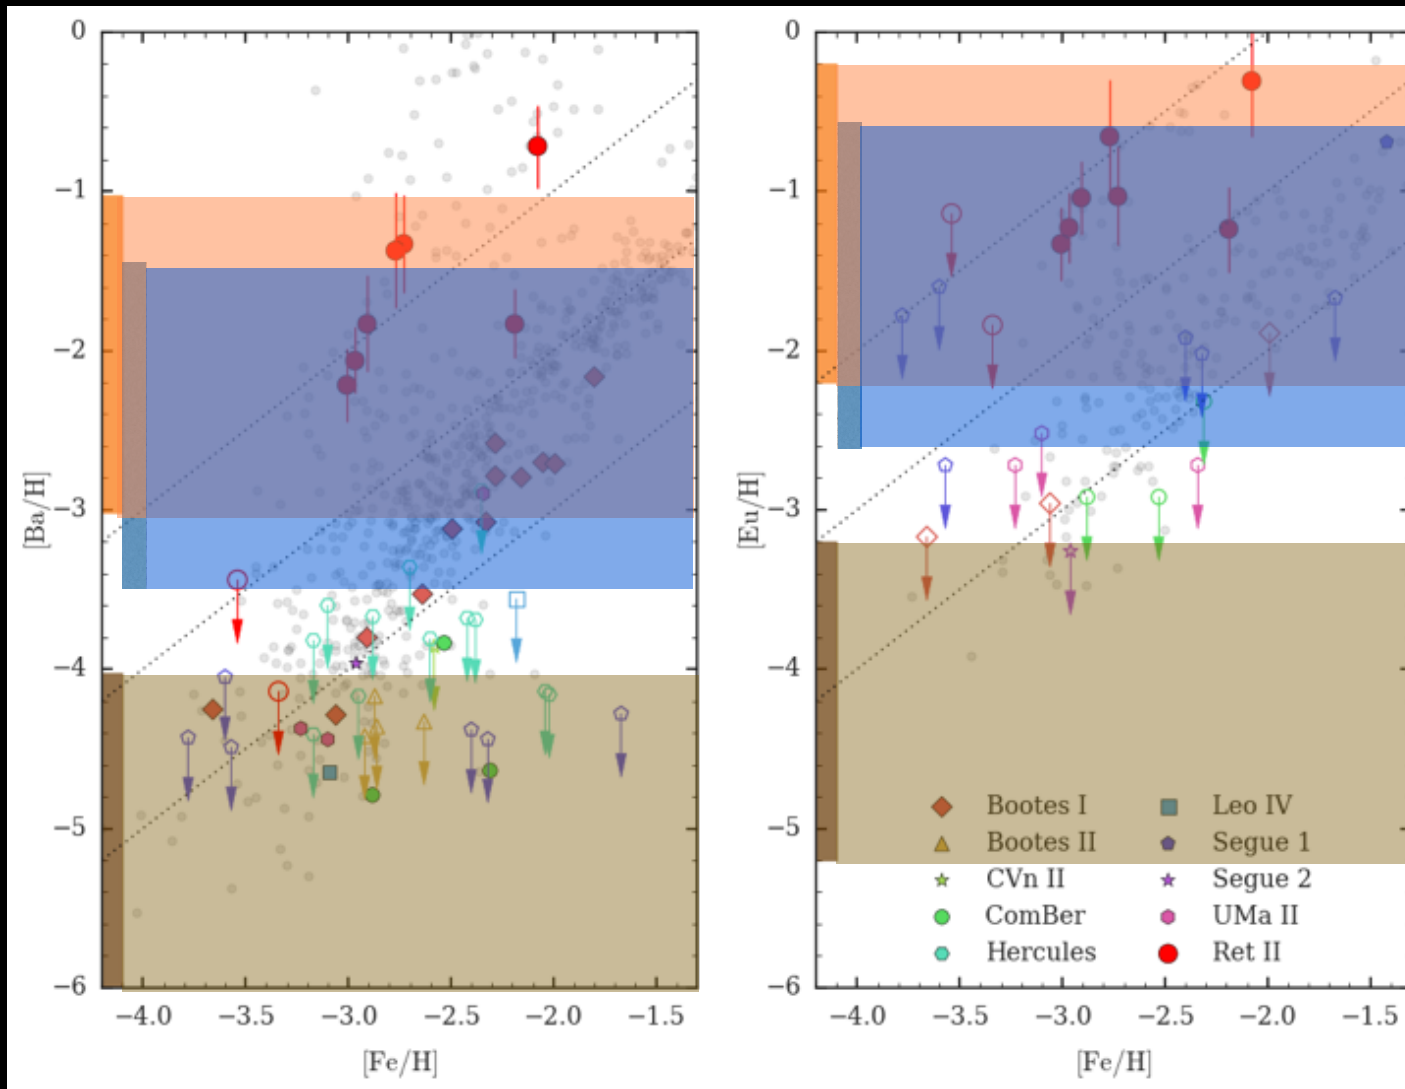

Supernova

# Rare and prolific supernovae also allowed Jet supernovae from magnetorotational instability

Neutron star  
merger

Supernova

Magnetar

e.g., Winteler et al. 2012

Reticulum II was enriched by a rare, prolific and possibly delayed r-process event

**A typical core-collapse supernova could not be responsible for the Ret II r-process signature!**

Can't you increase the # of SNe?

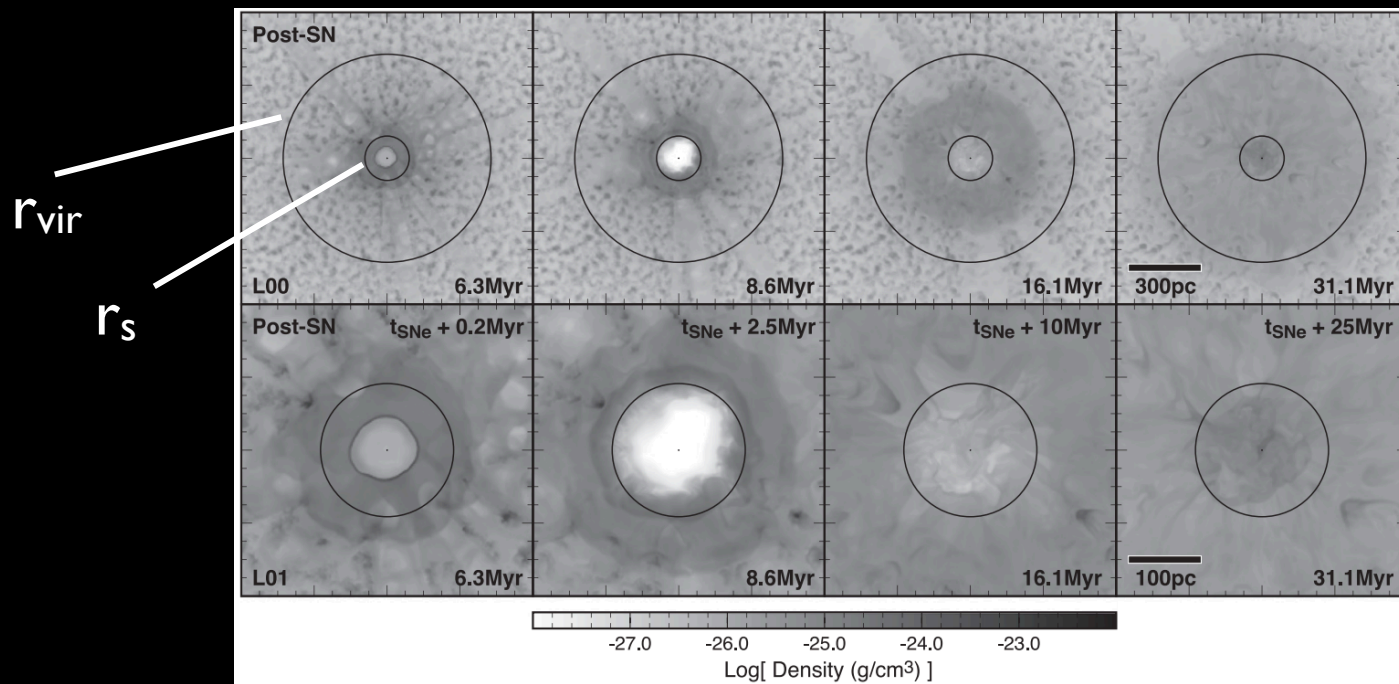

- ➔ No, 1000+ SNe would disrupt the system
- ➔ Need to be one/few massive events

Aren't NSM taking too long to enrich the galaxy?

- ➔ After the few (initial) SNe it takes time for the system to reassemble again (~100 Myr)
- ➔ Minimum time scales for coalescence is ~100 Myr

# Supernova feedback delays star formation in early galaxies

$10^{-6.5} M_{\text{sun}}$  halo (Bland-Hawthorn et al. 2015)

after SN

blow-out  
max

shells

re-accretion  
denser regions  
begin to form

# Dwarf galaxy archaeology

( = using an entire dwarf galaxy to study the early universe)

## How Rare?

Population of 10 UFDs:

➡ 1 of 10 r-process events

➡ Est. stellar mass of *all* UFDs:  
~2000 SNe expected

➡ Consistent w/ expected NSM  
rate of 1 per 1000-2000 SNe

# Dwarf galaxy archaeology

( = using an entire dwarf galaxy to study the early universe)

## How Rare?

### Population of 10 UFDs:

- ➔ 1 of 10 r-process events
- ➔ Est. stellar mass of *all* UFDs:  
~2000 SNe expected
- ➔ Consistent w/ expected NSM rate of 1 per 1000-2000 SNe

## How Prolific?

### Estimate gas mass of UFD:

Total gas in UFD galaxy

➔ Max. dilution mass:  $\sim 10^7 M_{\text{sun}}$

Gas swept up by a  $10^{51}$  erg energy injection into typical ISM

➔ Min. dilution mass:  $\sim 10^5 M_{\text{sun}}$

➔ Use with yields to compare to observations

# ASTROPHYSICAL ENVIRONMENT OF THE R-PROCESS

# ASTROPHYSICAL ENVIRONMENT OF THE R-PROCESS

# ASTROPHYSICAL ENVIRONMENT OF THE R-PROCESS

# Answers to the Big Question

## ★ What is the (dominant) astrophysical site of the r-process?

- ⇒ Core-collapse supernovae ⇒ Rare and prolific site
- ⇒ Neutron star mergers ⇒ Consistent w/ Ret II abundances
- ⇒ Others (e.g., magnetars) ⇒ Remain possible

## ★ What is the rate and yield of the event?

- ⇒  $\sim 1$  event per 2000 SN;  $\sim 10^{-2.5} M_{\text{sun}}$  of r-process

## ★ Does the dominant site change? ⇒ Probably not!

# Another puzzle: Chemical Enrichment in Ret II

**Need to explain: 7 r-process-rich, 2 n-capture poor stars**

- ➔ Sequential bursts of star formation?
- ➔ Inhomogeneous metal mixing?
- ➔ Accretion of other, smaller galaxy?

# The future is here

*The first glimpse of the incredible potential of UFDs for early universe studies*

## Near-field cosmology meets nuclear astrophysics

✓ Clean nucleosynthesis event(s) w/ actual information on the site and environment

➔ Unprecedented astrophysics constraints for nuclear physics, early chemical evolution, first galaxy formation, metal mixing processes, etc.

## Characterize the formation history of Ret II

➔ Need better abundances of (more) stars in Ret II

➔ Narrow down the identity of the rare and prolific r-process event (w/ better data and **better predictions**)

# Looking ahead

## "See the forest for the trees"

Re-interpreting population of r-process halo stars in the context of a dwarf galaxy environment

- ➔ *Where did these halo stars originate?*
- ➔ *Do they uniquely trace a 1/10 UFD population?*
- ➔ *Can we use them to trace the early assembly of the Milky Way/the low-metallicity tail of the MW MDF?*
